

# **Insect Pests of Cucurbits in New Hampshire**

**Alan T. Eaton and George Hamilton  
UNH Cooperative Extension**

**Cucurbit School Jan 11, 2017**

# **Insect Pests of Cucurbits in NH**

**Squash bug**

**Squash vine borer**

**Striped cucumber beetle**

**Seed corn maggot**

**Twospotted spider mites**

**Squash bug has 1  
gen./year**

**Look at base of  
plants and leaf  
undersides.**

**Destroy crop residues  
right after harvest.**

**Eggs are mostly on underside of leaves and towards base of plant.**

**The nymphs are whitish.  
They are the stage that is  
most vulnerable to sprays.**

**Spunbonded row covers** can control squash bugs until flowering.

**Rotate, destroy debris (in fall) under which adults might overwinter.**

**Cover plants before bugs appear.**

**Remove to allow pollinators in.**

**Pesticide choices (Squash bug) include**

**Sevin XLRplus 1**

**Asana, Azera, Danitol, Declare, Mustang,  
Pounce, Pyganic, Pyrenone, Warrior,  
Venom 3,3a**

**Assail, Sivanto 4a, 4d**

**Surround 25**

**Neemix, Azatin (for small nymphs)**

**Threshold: avg 1 egg mass/plant**

## **Tips:**

**Aim towards base of plants, esp. undersides of leaves. Covering tops of leaves does little for SqB.**

**Destroying crop debris promptly after harvest really helps, along with rotation.**

**Perimeter trapping ?**

# Squash Vine Borer

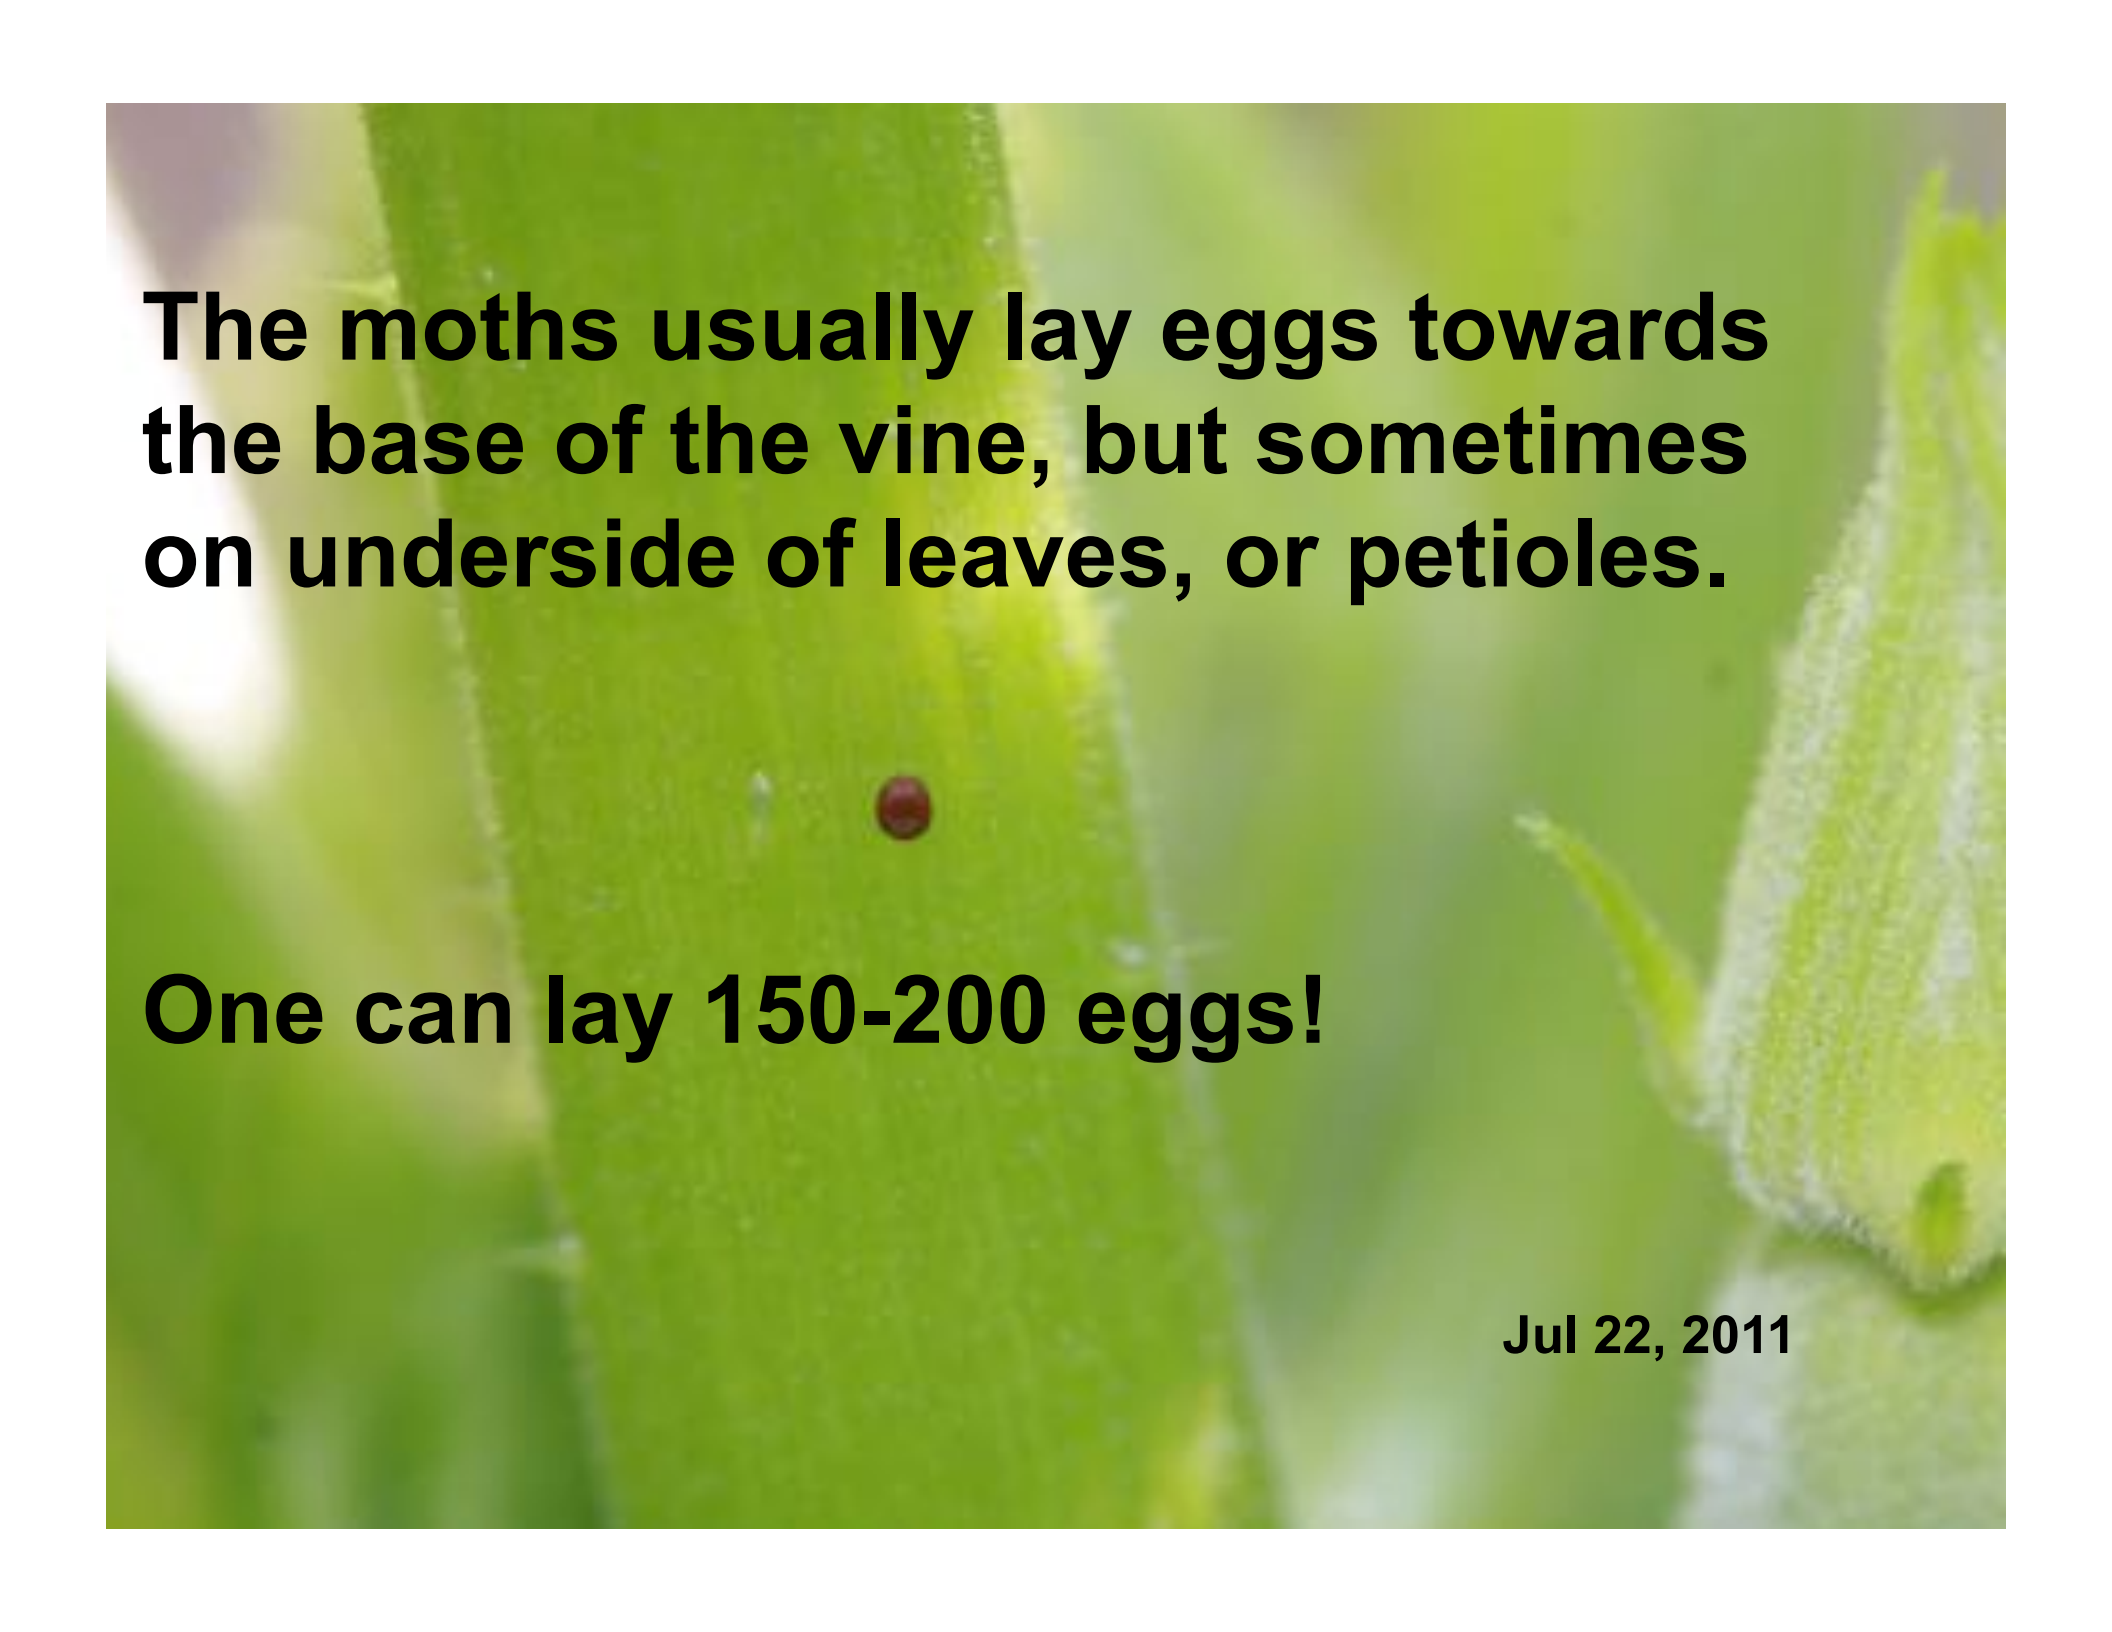

**1 gen./year**

**Overwinter as larva or pupa, in soil, 2”  
down**

**Rotation can help (overwinter in soil where  
you grew them last year). A short  
distance helps very little. Long distance  
helps more.**

A close-up photograph of a green plant stem, likely a vine, showing a single small, reddish-brown egg attached to the surface. The background is a soft-focus green, suggesting other parts of the plant or foliage.

**The moths usually lay eggs towards the base of the vine, but sometimes on underside of leaves, or petioles.**

**One can lay 150-200 eggs!**

Jul 22, 2011

Larvae bore through vines, stems,  
sometimes in fruit of pumpkin & hard  
squash.

Aug 27, 2011

**Aug 6, 2011**

**Squash and pumpkin varieties vary greatly in their “susceptibility” to SVB.**

**How? From preference of the moths when laying eggs, survival of larvae, and/or from the plant withstanding the damage.**

- **Zucchini & summer sq. *very susc.* *C. pepo***
- **Pumpkins are *susc.* *Cucurbita pepo***
- **Butternut (*C. moschata*) not preferred, and larvae don't survive well. “*resistant*”**
- **Giant pumpkins & Kubocha sq (*C. maxima*) are *susc.***

**Bush-type varieties seem to suffer more than vine-types, within the same group. George Hamilton notes that vine-type plants often root at the nodes. This may lessen the effect of attacks.**

**Deep plowing in fall or spring can kill many pupae (usu. abt 2" down).**

**If SERIOUS problem, consider skipping 1 year of susceptible squash or pumpkins.**

**Pesticides are effective if used starting June 26 or later. Vulnerable period lasts 4-5 weeks. Aim spray at the bases of the stems, and the vines, rather than foliage.**

**Spray late in day, to minimize risk to bees.**

**The products vary in their protection period, so see labels. Most last for 1 week, Pyrenone only 3-4d.**

**Some sites & crops might have even longer risk period.**

**Pesticide choices (Sq. vine borer) include**

**Asana, Azera, Danitol, Mustang, Pounce,  
Pyganic, Pyrenone, Warrior 3,3a**

**Assail 4**

**Vetica 16 & 28**

**Neemix ?**

**Pesticide must kill adults, or eggs,  
larvae before they get inside the vine.**

**Target: esp toward plant bases, rather  
than tips.**

## **Organic growers:**

**Consider emphasizing butternut sq.**

**Row covers before flowering**

**Azera (Neem & Pyrethrins)**

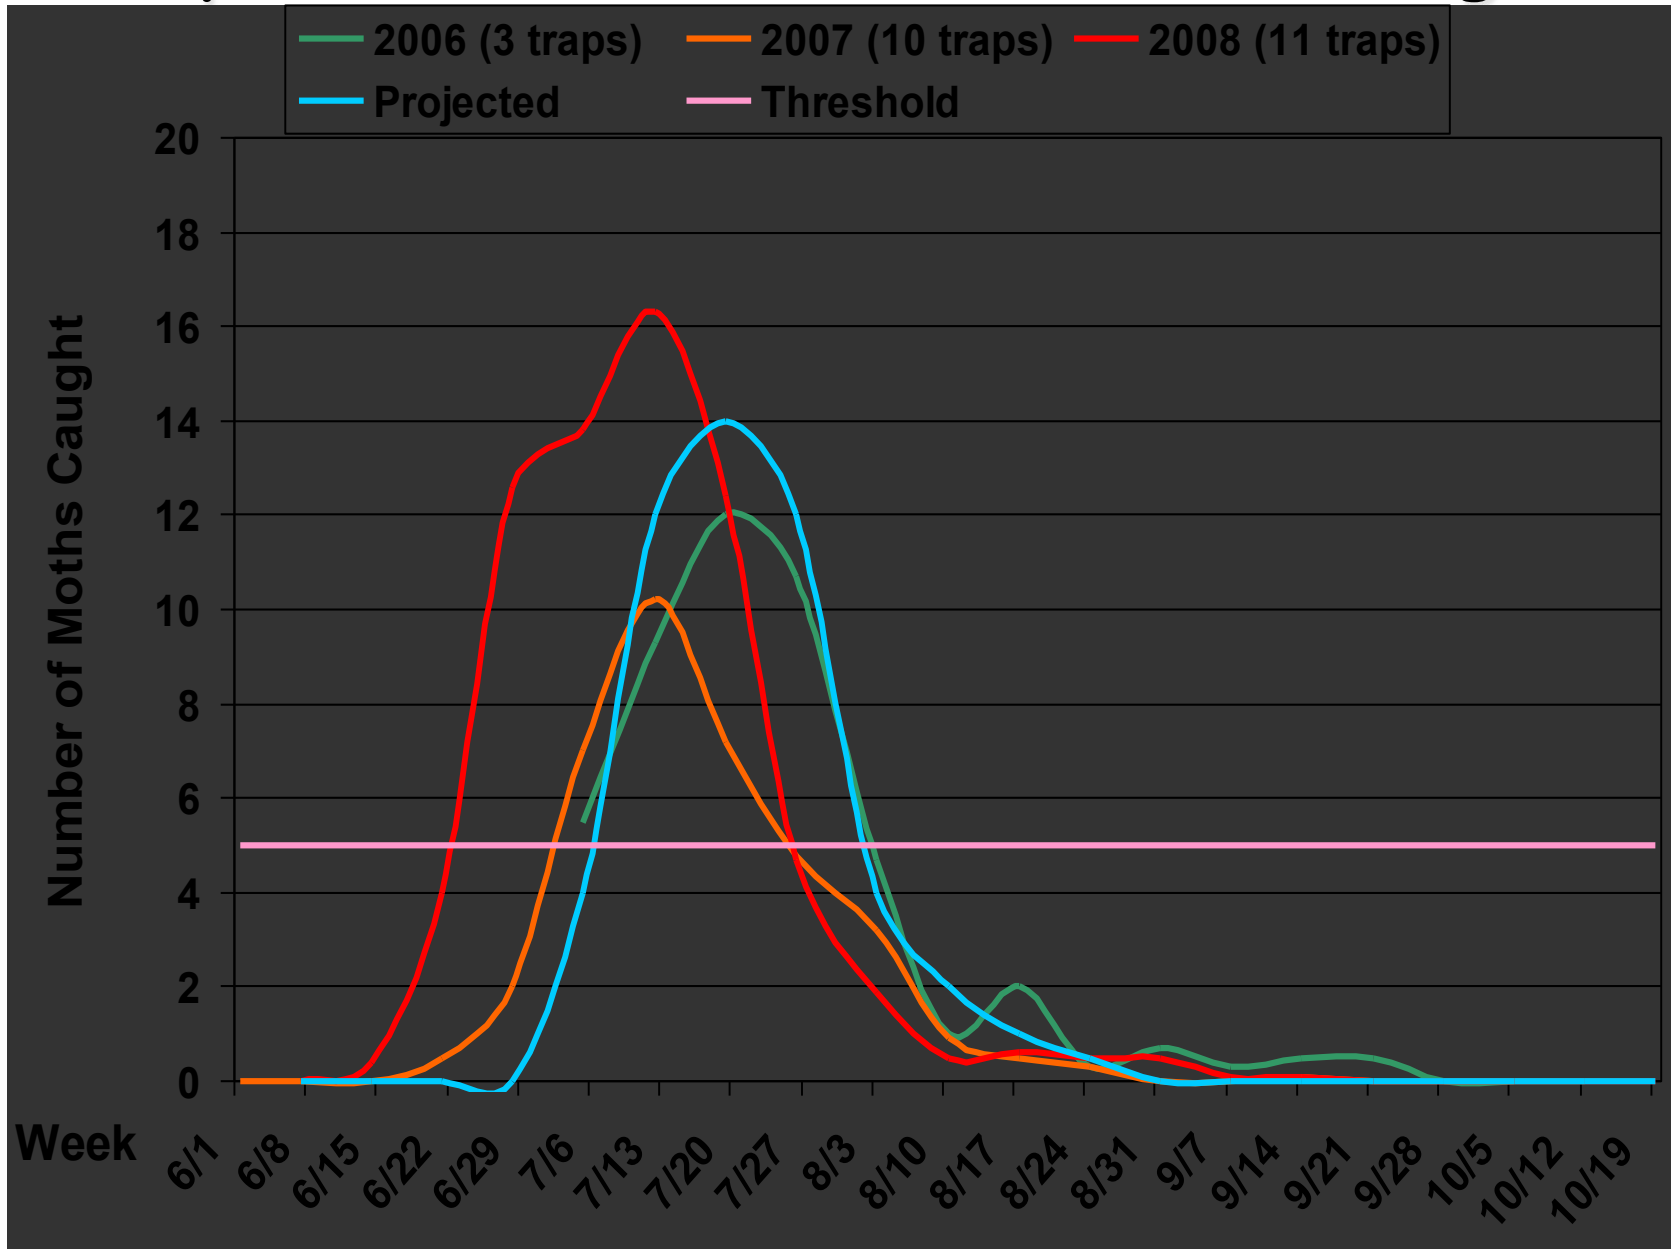

**Pyganic? Prob not effective**

A green tractor pulling a white tank sprayer through a cornfield. The tractor is moving from left to right, and a large plume of white mist is being sprayed from the tank. In the background, there is a small yellow building with a blue roof and a field of tall grasses. The sky is clear and blue.

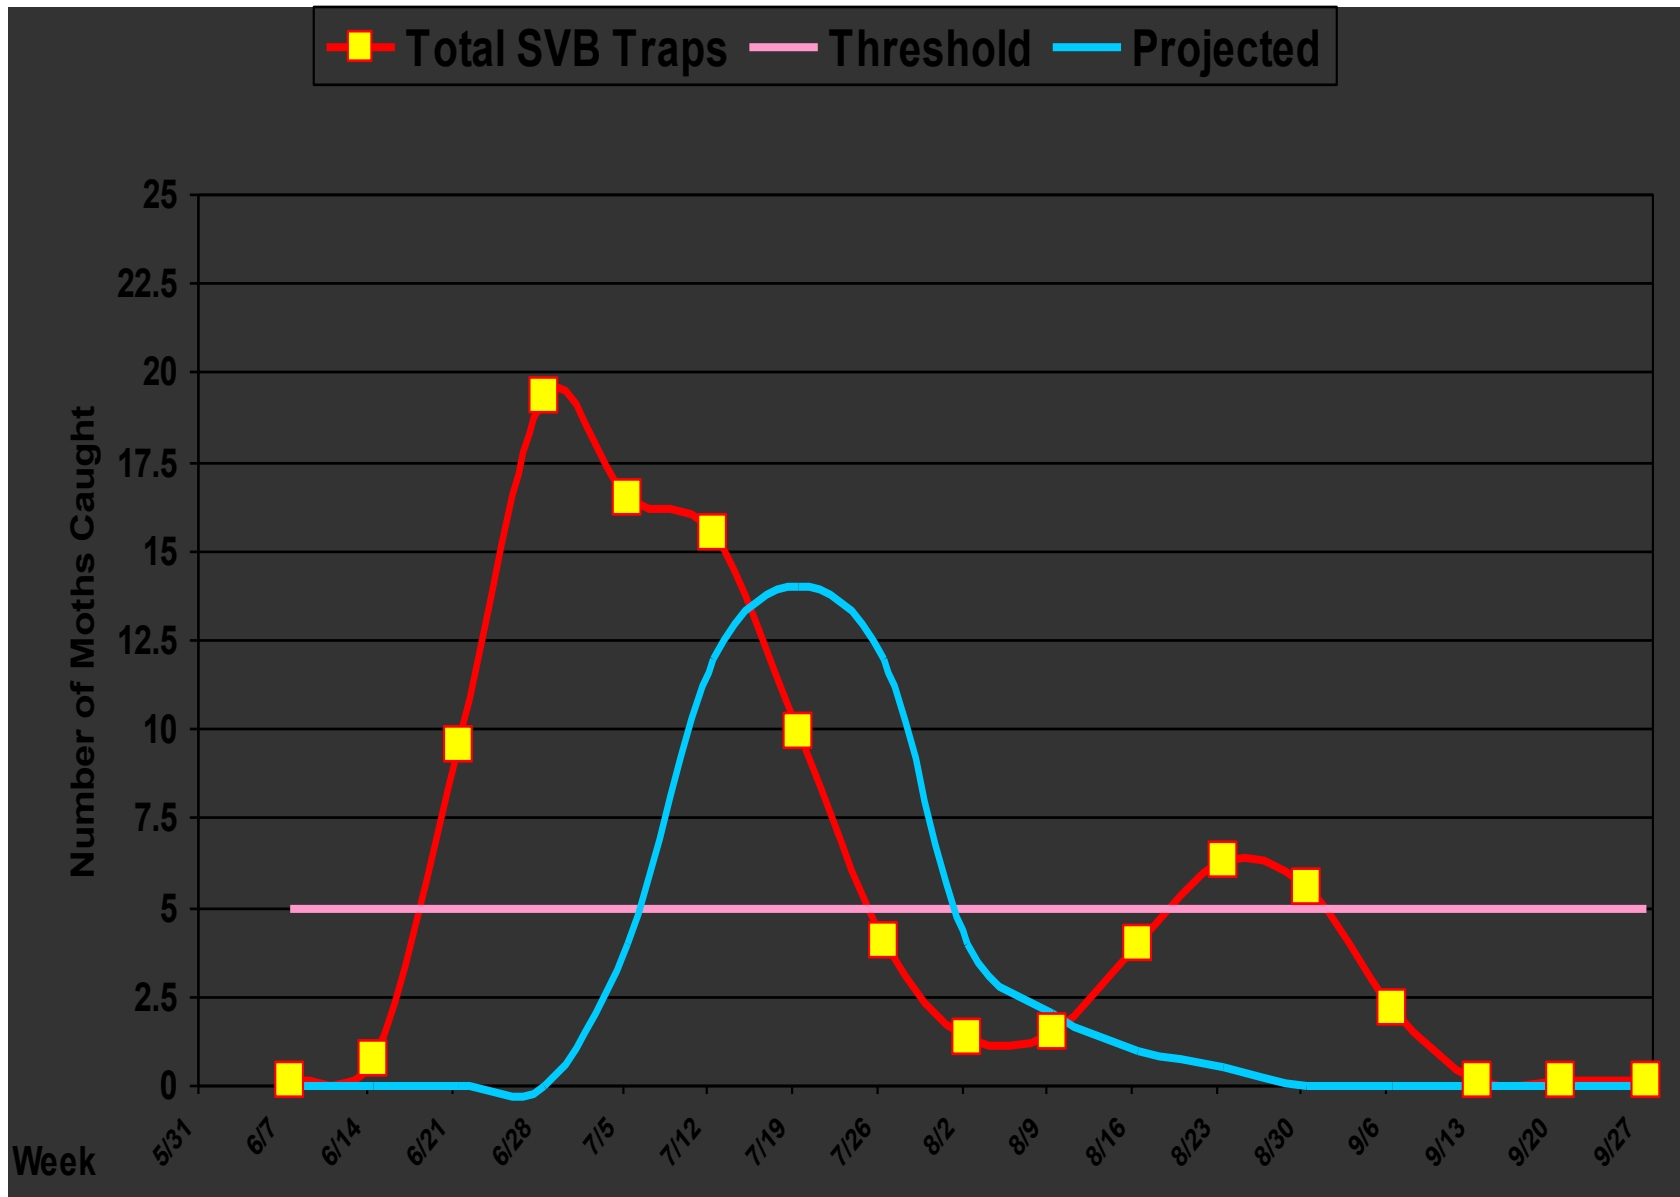

**In Southern NH:  
Jun 26 through Aug 5**

**Northern NH:  
June 30- Jul 30?**

# Squash Vine Borer - Male Moths Caught

# 2010 Squash Vine Borer - Male Moths Caught

Vegetable Insect IPM Summary

**Squash bee**

***Peponapis pruniosa* (Say)**

## Protecting pollinators

Sq/Pumpk flowers usu. close in afternoon, so most pollinator activity is in morning.

Wait until dusk to spray (protects honey bee and many squash & bumble bees).

Avoid spraying sq/pumpk in the morning.

Select toxicants with low bee toxicity.

Spray insecticides only when needed.

**Spraying Sq Bug: the most effective (and difficult) part is: hit the undersides of the foliage.**

| <u>Pesticide</u>                                          | <u>Target Stages</u> | <u>Bee Risk</u> |
|-----------------------------------------------------------|----------------------|-----------------|
| Assail                                                    | Ad & Nymphs          | M               |
| Thionex                                                   | Ad, Nymphs           | M until 7/31/15 |
| Sevin XLR                                                 | Ad, Nymphs           | H               |
| Asana, Warrior, Pounce, Brigade, Declare, Mustang & Venom | Ad, Nymphs           | H               |
| Sivanto (Sq bug only)                                     |                      | L               |
| Neemix                                                    | Nymphs               | M               |
| Pyrenone                                                  | Nymphs               | M               |
| Soap?                                                     | Nymphs               | L               |
| Surround?                                                 | Ad & Nymphs          | L               |

The pesticides on the preceding slide can be used on Squash vine borer too. Another (new) choice for SVB (but not squash bug) : Vetica (combination product)... has Low bee risk

So... lowest bee risk (& effective for Squash Vine Borer): **Assail** (Mod bee risk); **Vetica** (Low bee risk)

Low risk to bees, but not so good on SVB:  
**Neemix, Pyrenone**

# New!

Research by Jude Boucher (Univ CT) in summer 2016 showed that a single application of **Coragen** (group 28, 5 oz rate) in soil at planting time controlled SVB in summer squash!!

This product should have pretty low pollinator risk.

No, it did not work well on pumpkins. They root at multiple points (nodes) on vines, so probably did not pick up & translocate the material well.

**Striped cucumber beetle  
over-winters  
as an adult.**

**1 generation per year**

Smell of cucurbits: strong lure for stripers

Frequent monitoring soon after setting plants is a good idea.

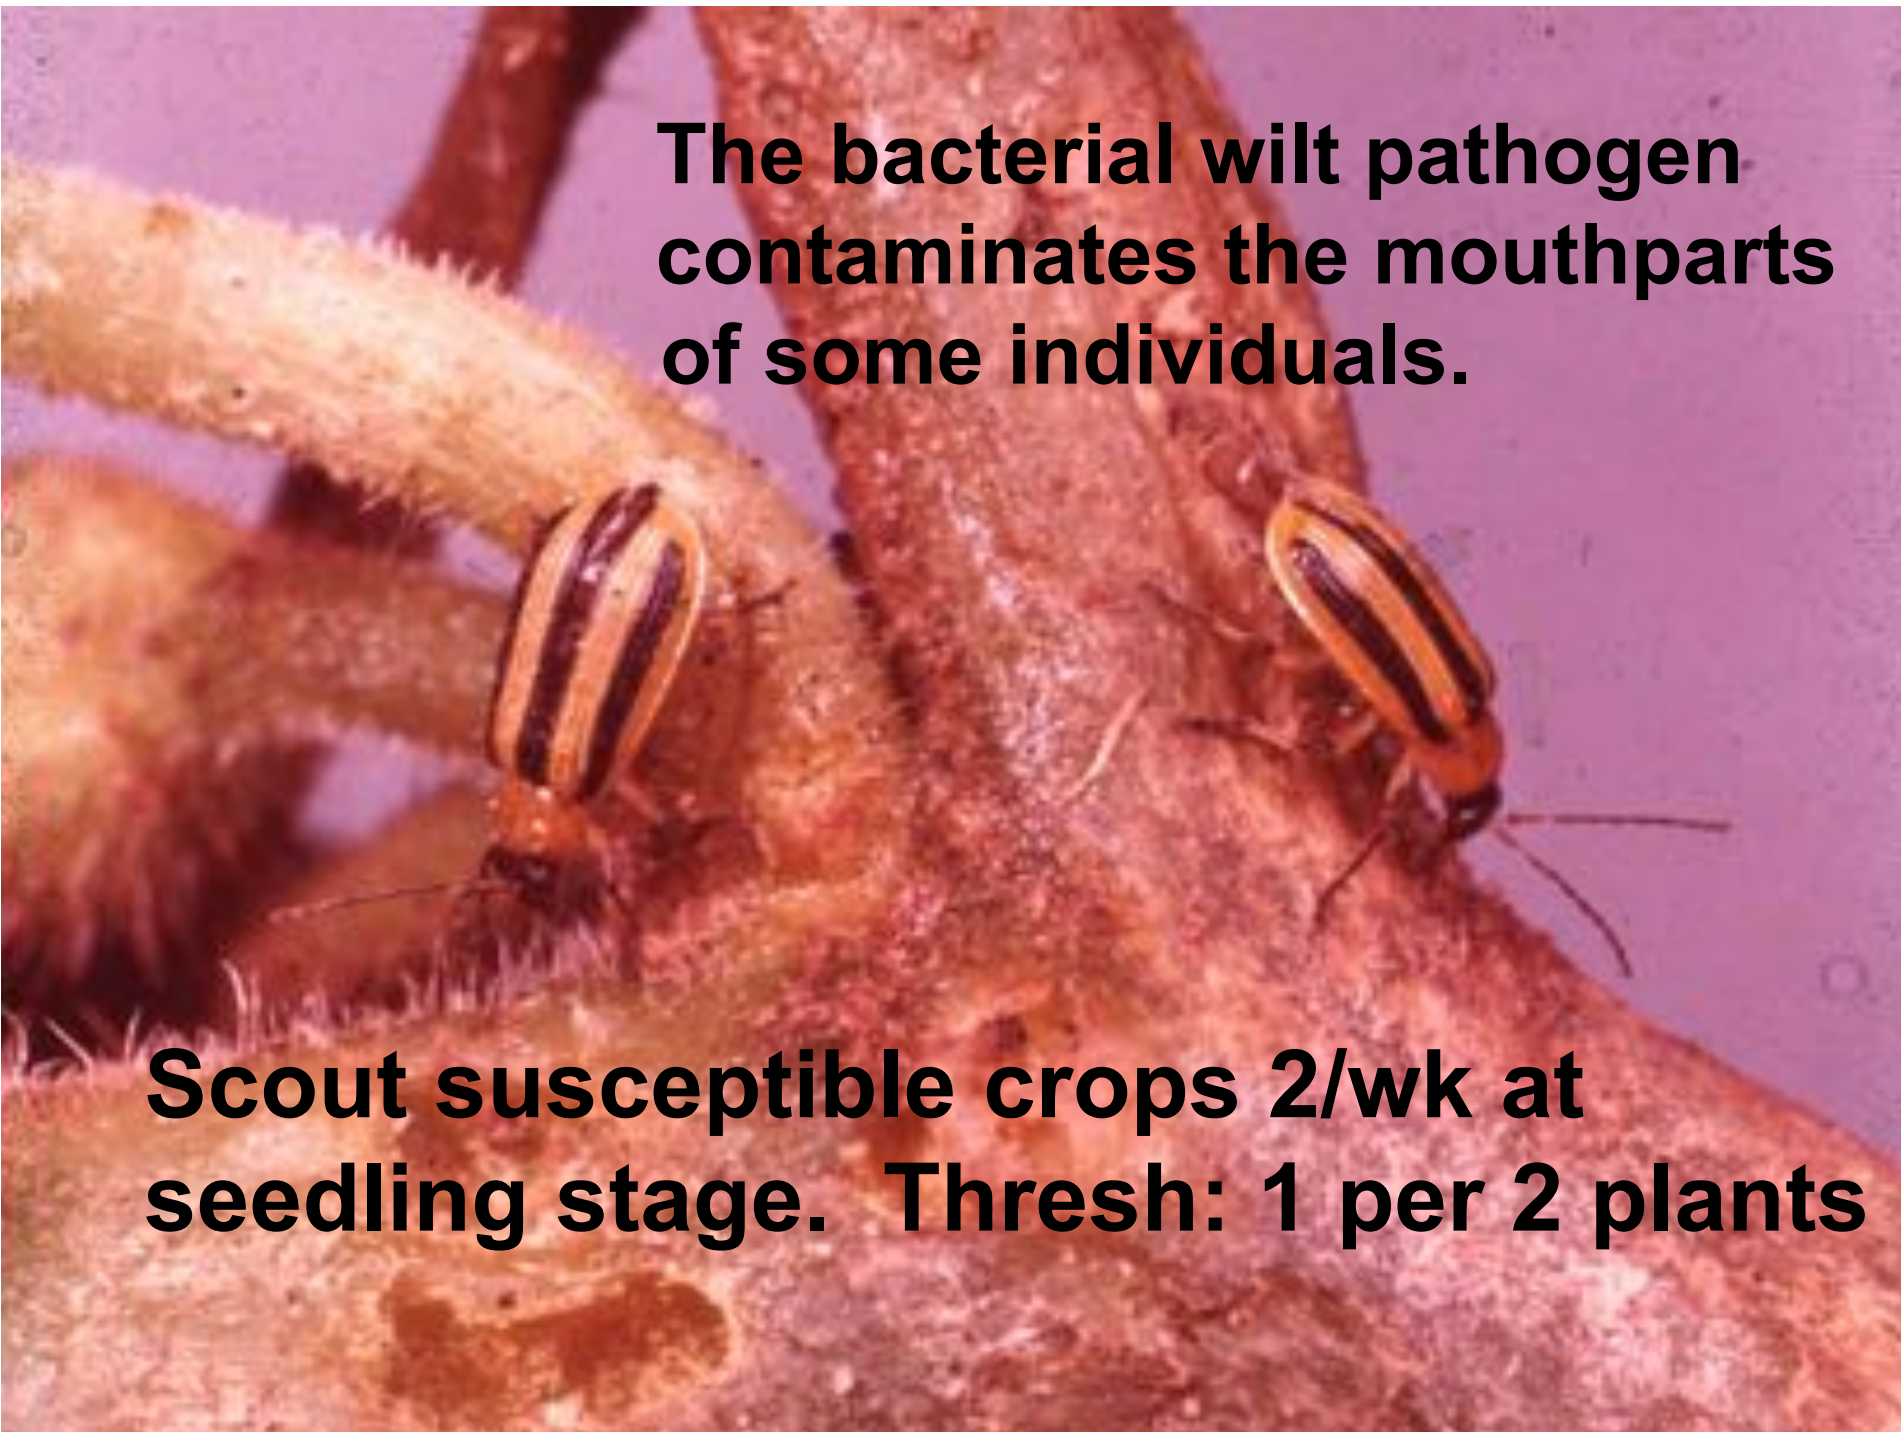

Row covers help... remove when flowers appear.

Heavy injury **early** really sets plants back.

**Muskmelon is highly susceptible to bacterial wilt, which is spread by stripers.**

A close-up photograph of two striped beetles, likely the Colorado potato beetle, on a reddish-brown, hairy plant stem. The beetles have yellow-orange bodies with dark longitudinal stripes. The background is a soft, out-of-focus purple.

**The bacterial wilt pathogen  
contaminates the mouthparts  
of some individuals.**

**Scout susceptible crops 2/wk at  
seedling stage. Thresh: 1 per 2 plants**

## **Pesticide choices (Cucumber beetles)**

**Sevin XLR plus, Lannate SP, MSR 1**

**Thionex ? 2a**

**Asana, Baythroid, Capture, Decis,  
Danitol, Mustang, Pounce, Pyganic,  
Pyrenone, Warrior 3,3a**

**Admire Pro, Assail, Platinum 4**

**Surround 25**

**Neemix ?**

**Consider treating very susc. plants right after removed from greenhouse, before being set in the field.**

**Organic growers:**

**Row covers before flowering**

**Monitor for adults when covers come off**

**Pyganic, Surround as insecticides**

## Seed Corn Maggot

- large seeded crops
- worst in cool, wet springs
- worst on soils with high OM content
- Manure really attracts the adults

**Adults look a lot like house fly.**

243-8

# Seed Corn Maggot

**1 generation/yr that is a problem (spring)**

**Direct seeding into high OM-content soil, with recent manure application, during cool, wet weather is riskiest pattern.**

**Setting transplants (rather than direct seeding) completely avoids the problem.**

**Questions?**
