# NEW HAMPSHIRE BEST LOG SGALING PRAGTIGES GUIDE 

University of New Hampshire COOPERATIVE EXTENSION

## INTRODUCTION

On June 21, 1999 twenty-two New Hampshire log scalers attended a workshop in Hillsboro, NH to discuss log-scaling practices. This group began the process of developing a voluntary log-scaling standard for NH . The knowledge and experience of this group of individuals combined with generally accepted industry standards described by the USDA, Forest Service in the "Log Scaling Handbook" and the Northeast Loggers' Association "Log Rules and Other Useful Information," will serve as the foundation for this guide.

Log scale is the basis for most business transactions between buyers and sellers of logs. A log scale, or rule, is an estimate of sawn lumber volume that can be obtained from a given log. Accurate, consistent and correct practices are essential for determining volume and fair market value. Log-scale can also be the source of confusion, frustration and suspicion. This guide will attempt to demystify the basics of $\log$ scaling by defining terms and working through the process of scaling a log.

New Hampshire does not currently license or certify log scalers, nor does the state have a law that specifically outlines $\log$ scaling procedures. However, the NH Division of Forests and Lands and NH Department of Agriculture, Weights and Measures Division have the authority to investigate inconsistent or deceptive log scaling practices.

I would like to thank those who reviewed this guide for accuracy and clarity. Special thanks goes to Laura Cooper and Don Winsor at HHP, Inc. for the fine pictures that demonstrate many of the scaling issues.

## INTERNATIONAL 1/4" LOG RULE:

In New Hampshire, the most common log rule used is the International $1 / 4^{\prime \prime} \log$ Rule. This rule measures to the nearest 5 board feet.

| Top Diameter of Log in Inches | Contents in Board Feet |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## LOG SCALING PROCEDURES

## Log Lengths

It is important that buyers and sellers of sawlogs understand the specifications being used in the market place. Each log buyer may have different log specifications based upon individual product requirements. Check with the mill first!

Knowing the required log lengths and minimum trim allowances for each market is critical to receiving the best price. Standard sawlog lengths are $8^{\prime}$ to $16^{\prime}$. Generally, sawlogs are bought and sold in $2^{\prime}$ increments. Some mills purchase odd length logs and some mills purchase longer or shorter lengths. Trim allowances range from $4^{\prime \prime}$ to $6^{\prime \prime}$ in addition to the standard length. Veneer, pulp, boltwood and other markets have very different requirements.

It is essential to understand length requirements for each market prior to bucking.

- Sawlog length is the length of the log plus whatever trim allowance is required by purchaser.
- Angled cuts: length is measured from the short side.
- Open face felling method (70-90 notch angle), when properly applied, will not affect the scaling cylinder.
- Sawlogs that exceed maximum log rule length should be scaled as two or more segments.
- To determine odd lengths, average the two nearest even lengths (on the rule).

## Log Diameters

When measuring the diameter of a sawlog, the scaler must:

- Measure log diameters inside the bark at the small end of the log.
- Measure through the true center of the log, not the center as indicated by growth rings.
- Measure as though the sawlog is a cylinder (as though bumps and depressions do not exist).
- Measure diameter by holding the scale stick flush to the end of the log when the sawlog is cut flush.
- Take two diameter measurements at right angles to each other. The first being the shortest axis.
- When averaging two measurements to determine the diameter round to the nearest inch. If both measurements are on the $1 / 2^{\prime \prime}$, round one down and the other up.
- If the average of two points for the diameter measures is calculated and results in a $1 / 2^{\prime \prime}$ round down, next time round up.
- Crotched logs or logs with branch whorls causing flare should be scaled as though the log were a true cylinder.

20" Vertical Measure 18" Horizontal Measure Diameter = 19"

## Scaling Deductions

Defects or $\log$ characteristics that will reduce the volume of usable lumber sawn require that log scale deductions be made. These defects can occur naturally or as the result of logging or transportation damage. Defects are also responsible for loss of grade yield. However, grade loss does not affect the volume of a log. Grade indicates quality of wood, scale indicates volume of wood.

Defects that result in scaling deductions include:

```
rot
rotten knots
fire scars
logging damage
pitch pockets
shake
sweep
crook (severe sidebend)
insect holes
crotch
severe checks
seams
breakage
shatter
stump pull
(fiber pulled from butt log during felling)
cracks
split
spider heart
white pine weevil damage
```

## Method for applying scale deductions:

The following formula is used to calculate deductions for interior defects when using the International $1 / 4^{\prime \prime}$ Log Rule:

$$
\frac{\mathrm{W}^{\prime \prime} \times \mathrm{T}^{\prime \prime} \mathrm{x} \mathrm{~L}}{16}=\text { Deduction in board feet }
$$

$\mathrm{W}=$ width in inches
$\mathrm{T}=$ thickness in inches
$\mathrm{L}=$ length in feet (to the nearest 2 foot increment)
The length of an interior defect is always difficult to determine unless it projects through the entire length of the sawlog. Variations in species create further challenges in the assessment of volume deductions. Experienced scalers develop better judgement through practice and by observing logs as they are sawn.

Seam

Spider Heart
Spider Heart are decay infected cracks that occur in some standing trees. While not always visible in the standing tree, spider heart will result in a loss of lumber volume recovered in the butt log. The scaler will make a length deduction to compensate for lost lumber volume.

## Shake

Shake is a separation of wood fiber along the growth rings. As the log is sawn into lumber the boards tend to fall apart. Obviously, shake is a serious defect and if detected in the log will result in rejection or severe volume deduction.

## Butt rot

To determine the scale deduction for a distinct area of rot, square off the defect, as indicated in the picture. Use the formula from previous page (8): measure the length and thickness of defect area in inches, and estimate the length in feet. Divide the result by 16.
Example: If the log in the
 picture scaled 100 board feet and the defect was 6 " by 8 ", 2 feet long. The scale deduction would be:
$6 \times 8 \times 2 \div 16=6$ deduction

## Sweep

Sweep or sidebend requires a scale deduction. The formula for calculating the volume of the deduction is:

Maximum departure" $-2^{*}=\%$ deduction from gross scale Diameter

This example:
$\frac{6 "-* 2}{14}=29 \%$
*2" for slabs in 16', 1" for 8' $\log$
Please refer to log sweep deduction quick reference charts on back pages.

## White Pine Weevil Damage

The white pine weevil is an insect that attacks and kills the top of the main stem (leader) of the white pine. The result is that a side branch replaces the leader and causes a major deviation in the growth form. Many sawmills will cull (reject) weeviled logs, or the scale deduction will severely reduce the net volume. It is important to check with the mill to understand the treatment of weevil damage.

## Crotch

Cracks, seams, splits:
Surface defects only affect scale if they penetrate enough to reduce the lumber yield of a sawlog. The orientation of a crack is critical. As an example, if a crack follows the grain of the sawlog the scaling volume may not be reduced. Conversely, a spiral seam or a crack that wanders around a sawlog may substantially reduce the scaling volume.
In this picture, the seam affects approximately $1 / 4$ of the scaling diameter. Therefore $1 / 4$ of the volume is deducted.

10' Log Seep Deductions
